Supercomputers

Definition of a supercomputer:

- Fastest machine in the world at given task
- A device to turn a compute-bound problem into an I/O bound problem
- Any machine costing \$30M+
- Any machine designed by Seymour Cray

CDC6600 (Cray, 1964) regarded as first supercomputer

Supercomputer Applications

Typical application areas:

- Military research (nuclear weapons, cryptography)
- Scientific research
- Weather forecasting
- Oil exploration
- Industrial design (car crash simulation)
- Bioinformatics

All involve huge computations on large data sets

In 70s-80s, Supercomputer \equiv Vector Machine

Loop Unrolled Code Schedule

```
for (i=0; i<N; i++)
```

```
    B[i] = A[i] + C;
```

```
loop: fld f1, 0(x1)
      fld f2, 8(x1)
      fld f3, 16(x1)
      fld f4, 24(x1)
      add x1, 32
      fadd.d f5, f0, f1
      fadd.d f6, f0, f2
      fadd.d f7, f0, f3
      fadd.d f8, f0, f4
      fsd f5, 0(x2)
      fsd f6, 8(x2)
      fsd f7, 16(x2)
      fsd f8, 24(x2)
      add x2, 32
      bne x1, x3, loop
```

loop:

		fsd f6			
		fsd f7			
add x2	bne	fsd f8			

Vector Supercomputers

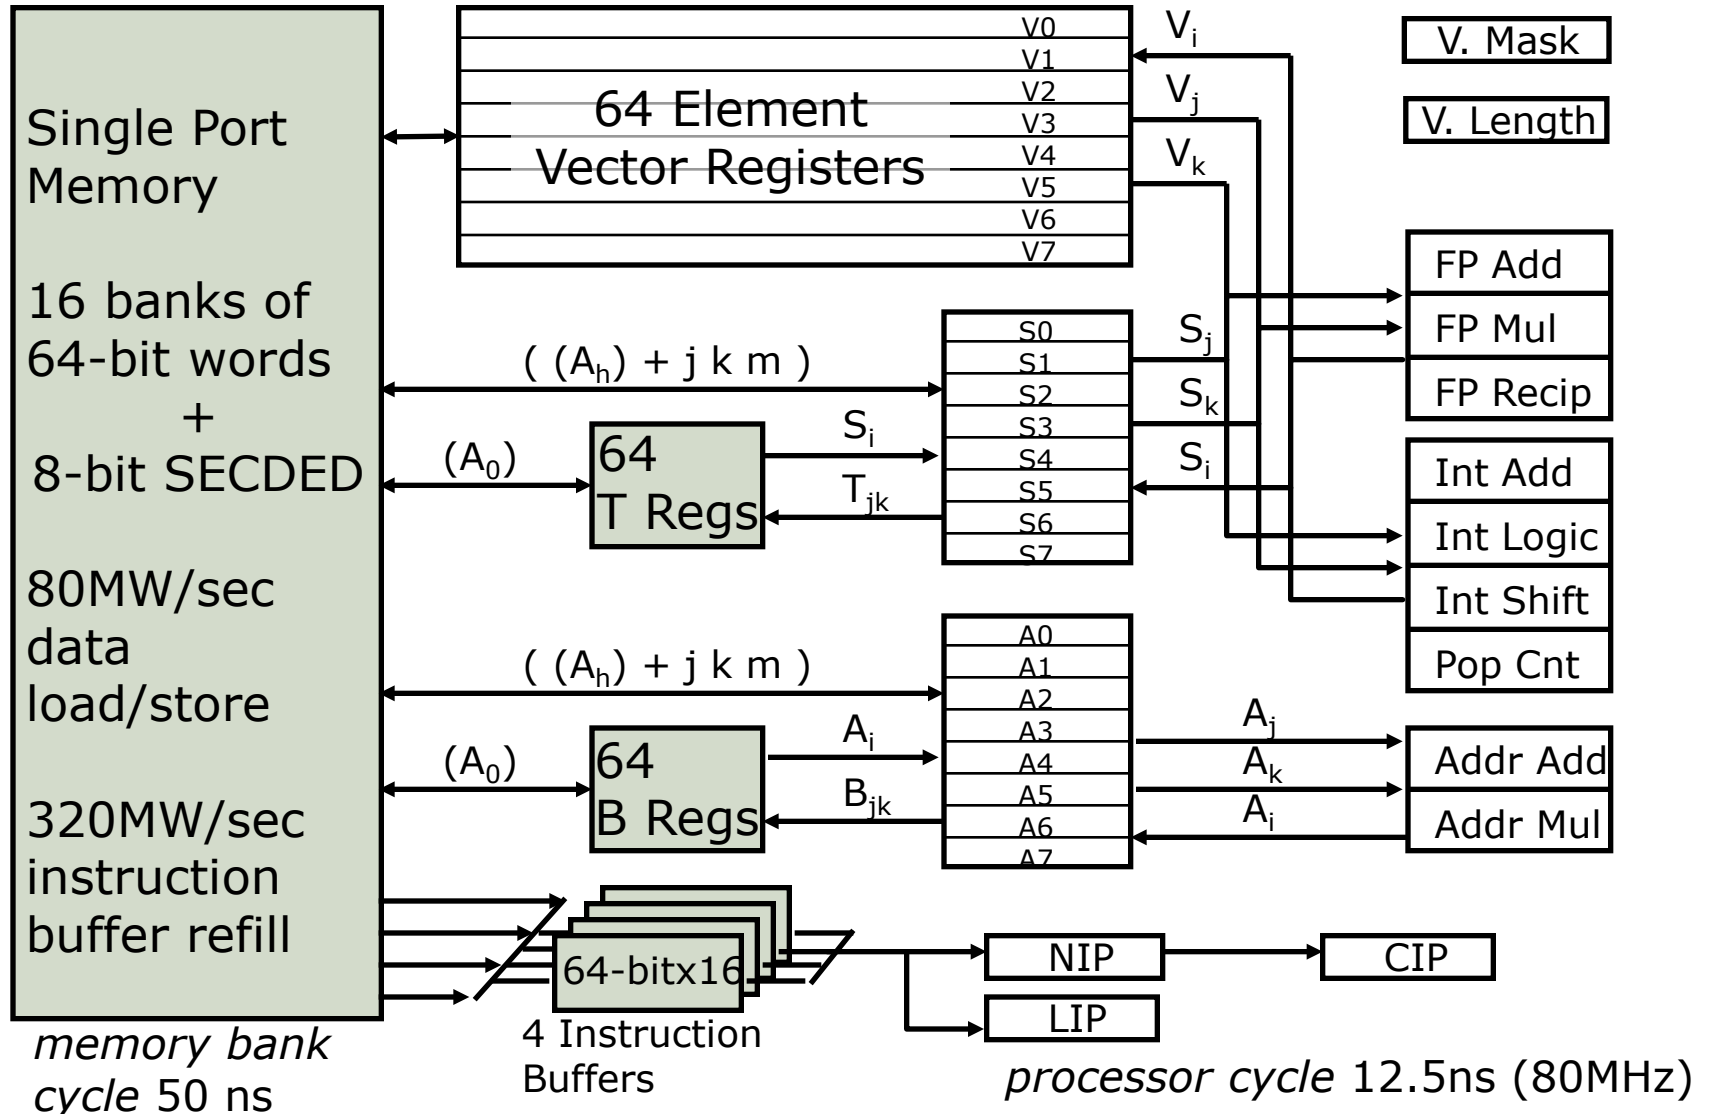

Epitomized by Cray-1, 1976:

- Scalar Unit
 - Load/Store Architecture
- Vector Extension
 - Vector Registers
 - Vector Instructions
- Implementation
 - Hardwired Control
 - Highly Pipelined Functional Units
 - No Data Caches
 - Interleaved Memory System
 - No Virtual Memory

Cray-1 (1976)

Vector Programming Model

Scalar Registers

Vector Registers

Vector Length Register

VLR

Vector Load and Store Instructions

LV v1, r1, r2

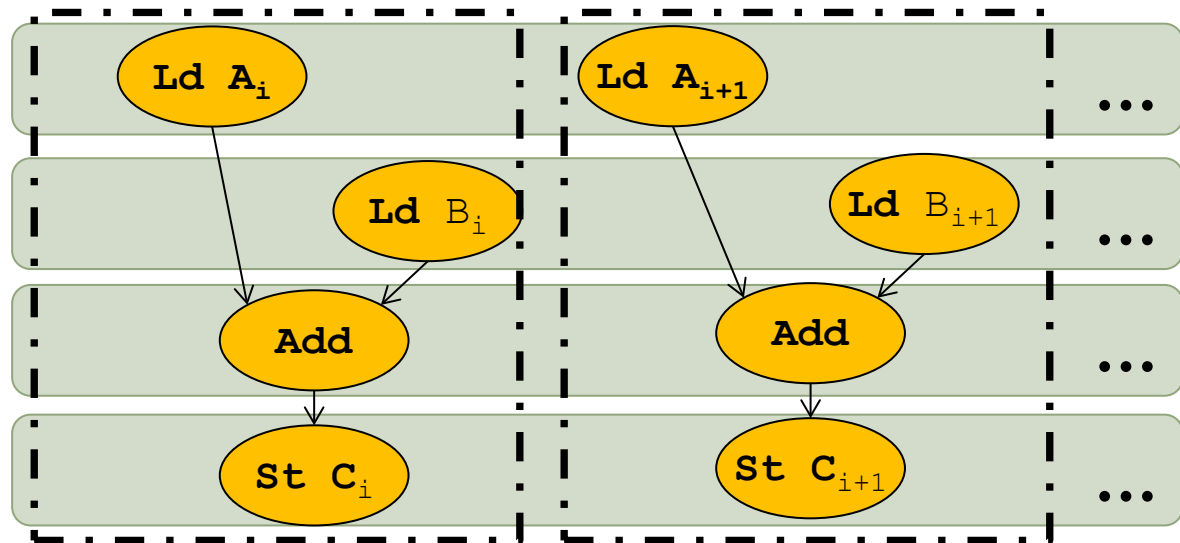

Compiler-based Vectorization

Scalar code

```
for (i=0; i<N; i++)  
    C[i] = A[i] + B[i];
```

Compiler recognizes independent operations with loop dependence analysis

Vector code

Vector Code Example

C code

```
for (i=0; i<64; i++)  
    C[i] = A[i] + B[i];
```

Scalar code

```
    LI x14, 64  
loop:  
    FLD f0, 0(x11)  
    FLD f2, 0(x12)  
    FADD.D f4, f2, f0  
    FSD f4, 0(x13)  
    ADDI x11, 8  
    ADDI x12, 8  
    ADDI x13, 8  
    ADDI x14, -1  
    BNEZ x14, loop
```

Vector code

```
LI vlr, 64  
LV v1, x11  
LV v2, x12  
ADDV.D v3, v1, v2  
SV v3, x13
```

How many
instructions?

Vector ISA Attributes

- Compact
 - One short instruction encodes N operations (plus bookkeeping)
- Expressive, tells hardware that these N operations:
 - Are independent
 - Use the same functional unit
 - Access disjoint elements in vector registers
 - Access registers in same pattern as previous instructions
 - Access a contiguous block of memory (unit-stride load/store)
 - Access memory in a known pattern (strided load/store)

Vector ISA Hardware Implications

- Large amount of work per instruction
 - Less instruction fetch bandwidth requirements
 - Allows simplified instruction fetch design
- No data dependence within a vector
 - Amenable to deeply pipelined/parallel designs
- Disjoint vector element accesses
 - Banked rather than multi-ported register files
- Known regular memory access pattern
 - Allows for banked memory for higher bandwidth

Vector Arithmetic Execution

- Use deep pipeline (\Rightarrow fast clock) to execute element operations
- Simplifies control of deep pipeline because elements in vector are independent (\Rightarrow no hazards!)

Six-stage multiply pipeline

Given 64-element registers, how long does it take to compute V3?

Vector Instruction Execution

ADDV C,A,B

*Execution using
one pipelined
functional unit*

A[6] B[6]
A[5] B[5]
A[4] B[4]
A[3] B[3]

*Execution using
four pipelined
functional units*

A[24] B[24] A[25] B[25] A[26] B[26] A[27] B[27]
A[20] B[20] A[21] B[21] A[22] B[22] A[23] B[23]
A[16] B[16] A[17] B[17] A[18] B[18] A[19] B[19]
A[12] B[12] A[13] B[13] A[14] B[14] A[15] B[15]

Vector Unit Structure

Vector Instruction Parallelism

Can overlap execution of multiple vector instructions

- example machine has 32 elements per vector register and 8 lanes

Complete 24 operations/cycle while issuing 1 short instruction/cycle

Vector Chaining

Problem: Long latency for RAW register dependencies

- Vector version of register bypassing
 - introduced with Cray-1

Vector Chaining Advantage

- Without chaining, must wait for last element of result to be written before starting dependent instruction

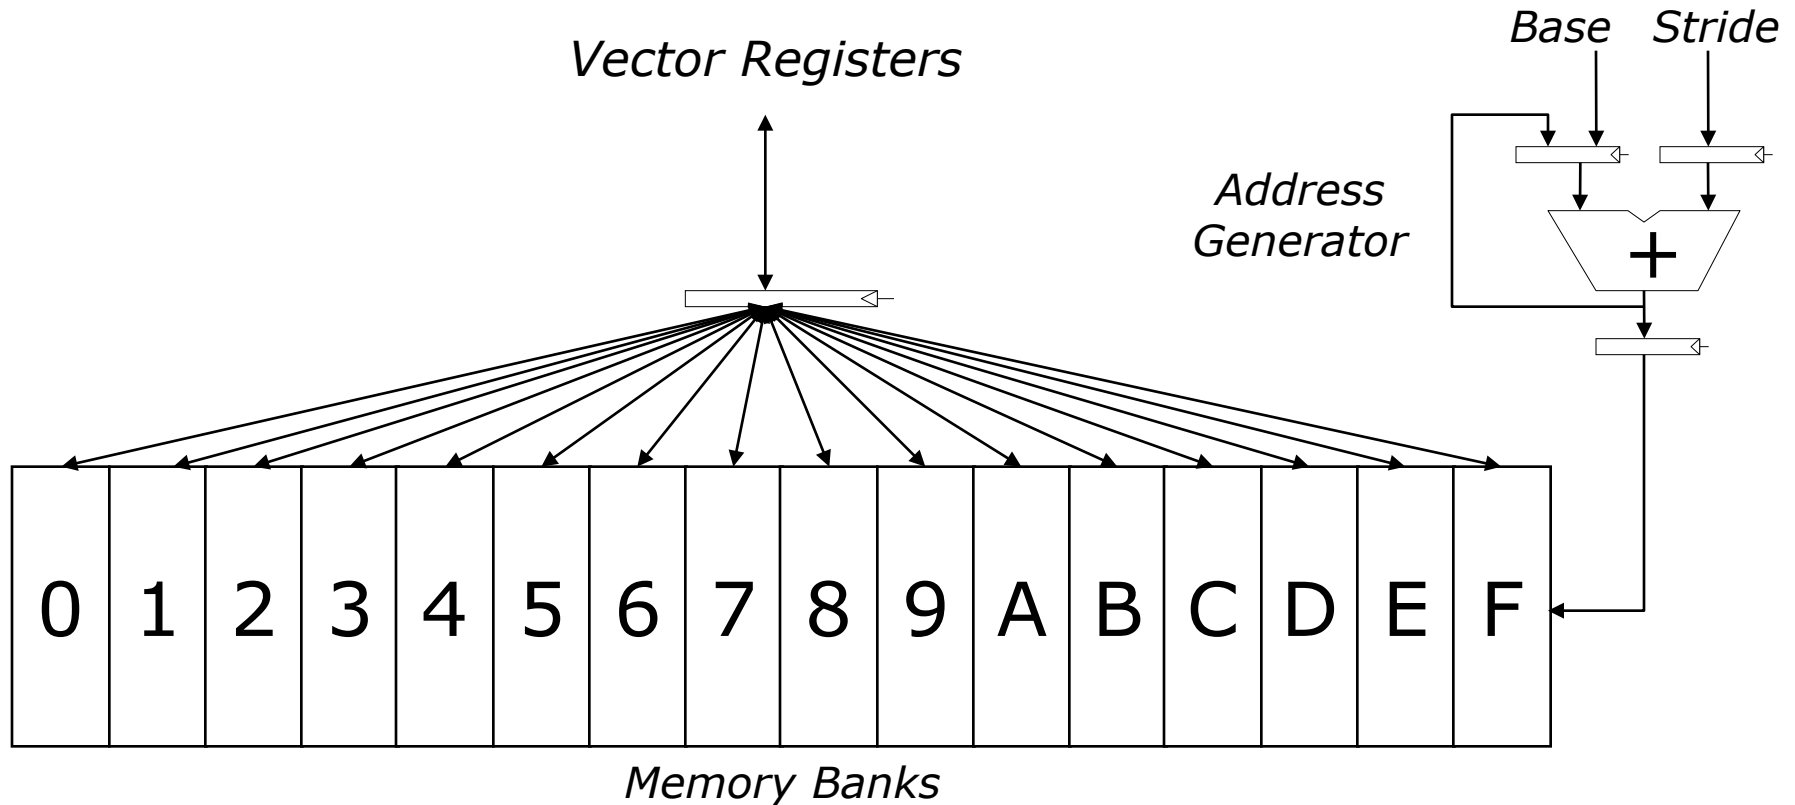

- With chaining, can start dependent instruction as soon as first result appears

Vector Memory System

Cray-1: 16 banks, 4 cycle bank busy time, 12 cycle latency

- *Bank busy time*: Cycles between accesses to same bank
- Allows 16 parallel accesses (if data in different banks)

Vector Stripmining

Problem: Vector registers have finite length

Solution: Break loops into pieces that fit in registers, "*Strip mining*"

```
for (i = 0; i < N; i++)  
    C[i] = A[i] + B[i];
```

```
ANDI x11, xN, 63      # N mod 64  
MTC1 v1r, x11         # Do remainder  
loop:  
    LV v1, xA  
    SLL x12, x11, 3     # Multiply by 8  
    ADD xA, xA, x12     # Bump A pointer  
    LV v2, xB  
    ADD xB, xB, x12     # Bump B pointer  
    ADDV.D v3, v1, v2  
    SV v3, xC  
    ADD xC, xC, x12     # Bump C pointer  
    SUB xN, xN, x11     # Subtract elements  
    LI x11, 64  
    MTC1 v1r, x11      # Reset full length  
    BGTZ xN, loop      # Any more to do?
```

Vector Conditional Execution

Problem: Want to vectorize loops with conditional code:

```
for (i = 0; i < N; i++)  
    if (A[i] > 0) then  
        A[i] = B[i];
```

Solution: Add vector *mask* (or *flag*) registers

- vector version of predicate registers, 1 bit per element

...and *maskable* vector instructions

- vector operation becomes NOP at elements where mask bit is clear

Code example:

CVM	# Turn on all elements
LV vA, xA	# Load entire A vector
SGTVS.D vA, f0	# Set bits in mask register where A>0
LV vA, xB	# Load B vector into A under mask
SV vA, xA	# Store A back to memory under mask

Masked Vector Instructions

Simple implementation

- execute all N operations, turn off result writeback according to mask

$M[7]=1$ $A[7]$ $B[7]$

$M[6]=0$ $A[6]$ $B[6]$

$M[5]=1$ $A[5]$ $B[5]$

$M[4]=1$ $A[4]$ $B[4]$

$M[3]=0$ $A[3]$ $B[3]$

$M[2]=0$

$M[1]=1$

$M[0]=0$

$C[2]$

$C[1]$

$C[0]$

Write Enable

Write data port

Density-time implementation

- scan mask vector and only execute elements with non-zero masks

$M[7]=1$

$M[6]=0$

$M[5]=1$

$M[4]=1$

$M[3]=0$

$M[2]=0$

$M[1]=1$

$M[0]=0$

$A[7]$ $B[7]$

$C[5]$

$C[4]$

$C[1]$

Write data port

$$C[i] = A[i] + B[i]$$

Vector Scatter/Gather

Want to vectorize loops with indirect accesses:

```
for (i = 0; i < N; i++)  
    A[i] = B[i] + C[D[i]]
```

Indexed load instruction (Gather)

```
LV vD, xD           # Load indices in D vector  
LVI vC, xC, vD       # Load indirect from xC base  
LV vB, xB           # Load B vector  
ADDV.D vA, vB, vC    # Do add  
SV vA, xA           # Store result
```

Is this a correct translation?

Vector Scatter/Gather

Scatter example:

```
for (i = 0; i < N; i++)  
    A[B[i]]++;
```

Is the following a correct translation?

```
LV vB, xB          # Load indices in B vector  
LVI vA, xA, vB      # Gather initial A values  
ADDV vA, vA, 1      # Increment  
SVI vA, xA, vB      # Scatter incremented values
```

A Later-Generation Vector Super: *NEC SX-6 (2003)*

- CMOS Technology
 - 500 MHz CPU, fits on single chip
 - SDRAM main memory (up to 64GB)
- Scalar unit
 - 4-way superscalar
 - with out-of-order and speculative execution
 - 64KB I-cache and 64KB data cache
- Vector unit
 - 8 foreground VRegs + 64 background VRegs (256x64-bit elements/VReg)
 - 1 multiply unit, 1 divide unit, 1 add/shift unit, 1 logical unit, 1 mask unit
 - 8 lanes (8 GFLOPS peak, 16 FLOPS/cycle)
 - 1 load & store unit (32x8 byte accesses/cycle)
 - 32 GB/s memory bandwidth per processor
- SMP structure
 - 8 CPUs connected to memory through crossbar
 - 256 GB/s shared memory bandwidth (4096 interleaved banks)

Multimedia/SIMD Extensions

- Short vectors added to existing general-purpose ISAs
- Idea first used on Lincoln Labs TX-2 computer in 1957, with 36b datapath split into 2x18b or 4x9b
- Initial implementations often reused existing registers
 - e.g., 64-bit registers split into 2x32bits or 4x16bits or 8x8bits
- Trend towards larger vector support in microprocessors
 - e.g. x86:
 - MMX (64 bits)
 - SSEx (128 bits)
 - AVX (256 bits)
 - AVX-512 (512 bits/masks)

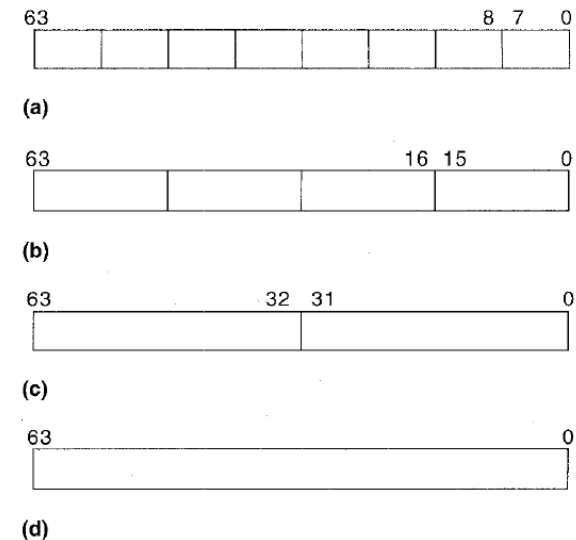

Figure 1. MMX technology data types: packed byte (a), packed word (b), packed doubleword (c), and quadword (d).

Intel SIMD Evolution

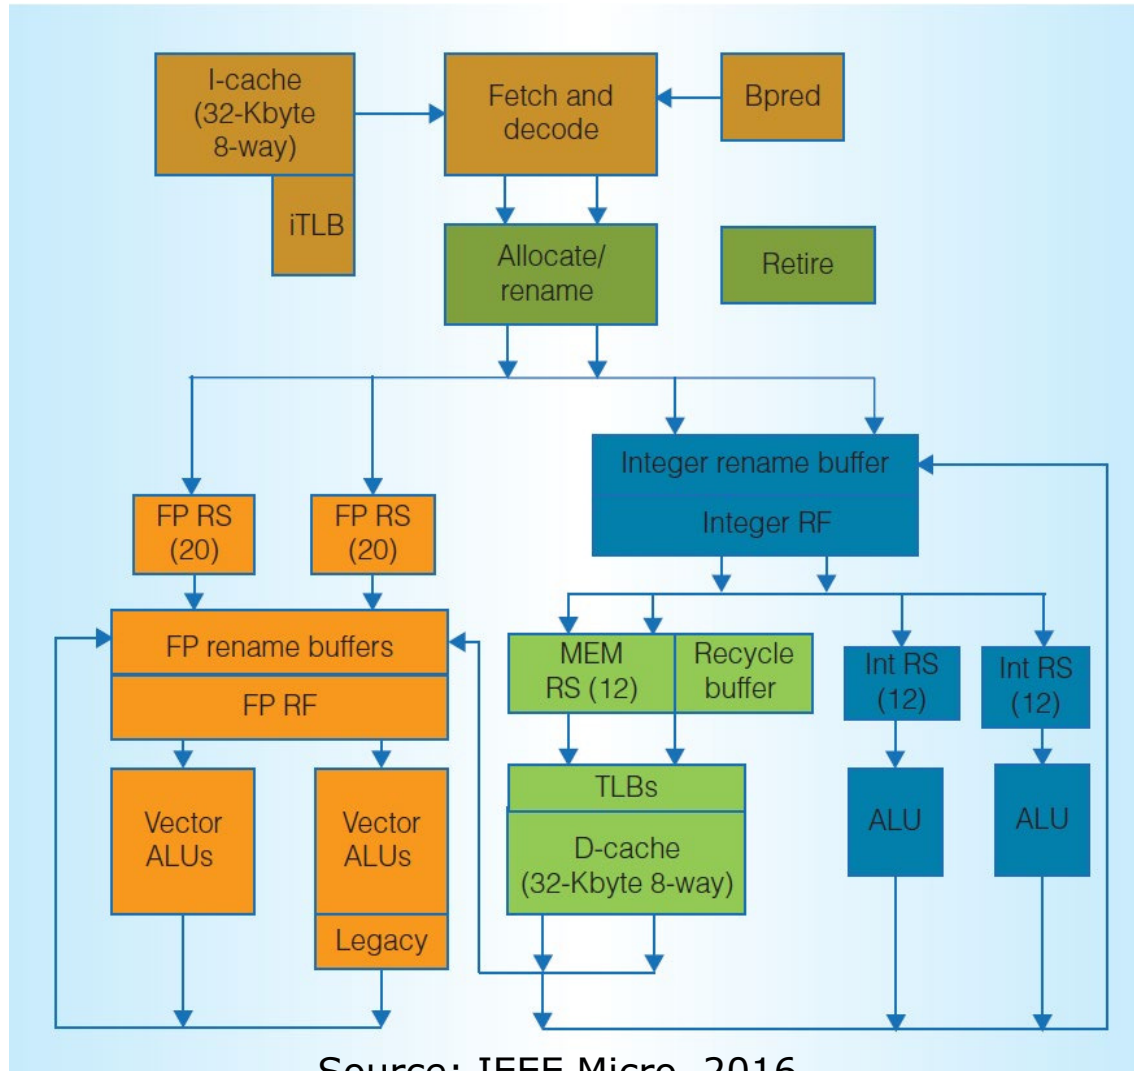

Implementations:

- Intel MMX (1996) – 64bits
 - Eight 8-bit integer ops, or
 - Four 16-bit integer ops
 - Two 32-bit integer ops
- Streaming SIMD Extensions (SSE) (1999) – 128bits
 - Four 32-bit integer ops (and smaller integer types)
 - Four 32-bit integer/fp ops, or
 - Two 64-bit integer/fp ops
- Advanced Vector Extensions (2010) – 256bits
 - Four 64-bit integer/fp ops (and smaller fp types)
- AVX-512 (2017) – 512bits
 - New instructions: scatter/gather, mask registers

Multimedia Extensions vs Vectors

- Limited instruction set
 - No vector length control
 - Usually no masks
 - Up until recently, no strided load/store or scatter/gather
 - Unit-stride loads must be aligned to 64/128-bits
- Limited vector register length
 - requires superscalar dispatch to keep units busy
 - loop unrolling to hide latencies increases register pressure
- Trend towards fuller vector support
 - Better support for misaligned memory accesses
 - Support of double-precision (64-bit floating-point)
 - Support for masked operations

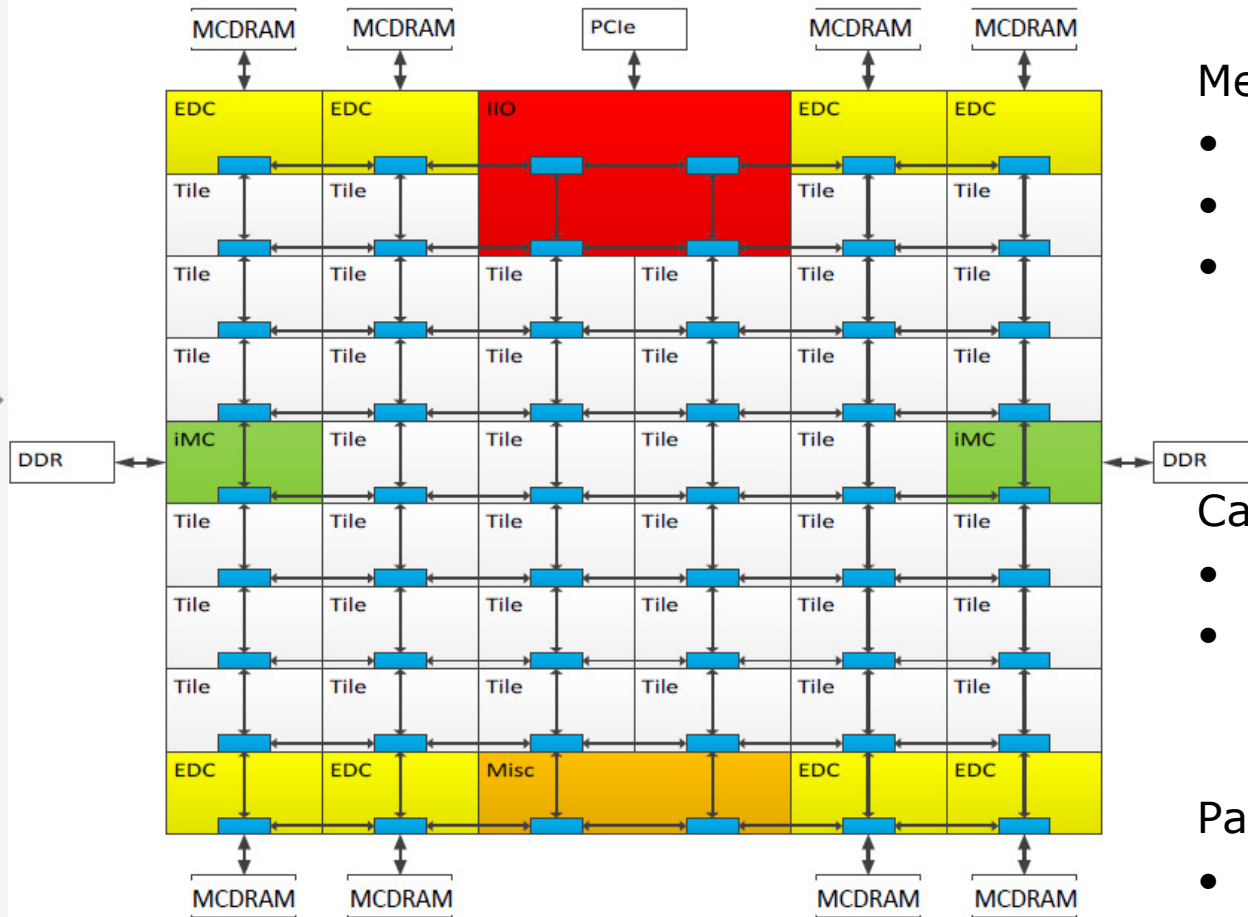

Knights Landing (KNL) CPU

Source: IEEE Micro, 2016

- 2-wide decode/retire
- 6-wide execute
- 72-entry ROB
- 64B cache ports
- 2 load/1 store ports
- Fast unaligned access
- Fast scatter/gather
- OoO int/fp RS
- In-order mem RS
- 4 thread SMT
- Many shared resources
 - ROB, rename buffer, RS: dynamically partitioned
- Several thread choosers

Knights Landing (KNL) Mesh

Source: IEEE Micro, 2016

Mesh of Rings

- Rows/columns (half) ring
- YX routing
- Message arbitration on:
 - Injection
 - Turns

Cache Coherent Interconnect

- MESIF protocol
- Distributed directory
 - to filter snoops

Partitioning modes

- All-to-all
- Quadrant
- Sub-NUMA

Thank you!
